# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## General Description

The MAX11646/MAX11647 low-power, 10-bit, 1-/2-channel analog-to-digital converters (ADCs) feature internal track/hold (T/H), voltage reference, a clock, and an I<sup>2</sup>C-compatible 2-wire serial interface. These devices operate from a single supply of 2.7V to 3.6V (MAX11647) or 4.5V to 5.5V (MAX11646) and require only 6 $\mu$ A at a 1ksps sample rate. AutoShutdown™ powers down the devices between conversions, reducing supply current to less than 1 $\mu$ A at lower throughput rates. The MAX11646/MAX11647 each measure two single-ended or one differential input. The fully differential analog inputs are software configurable for unipolar or bipolar and single-ended or differential operation.

The full-scale analog input range is determined by the internal reference or by an externally applied reference voltage ranging from 1V to V<sub>DD</sub>. The MAX11647 features a 2.048V internal reference and the MAX11646 features a 4.096V internal reference.

The MAX11646/MAX11647 are available in an ultra-tiny 1.9mm x 2.2mm WLP package and an 8-pin  $\mu$ MAX® package. These ADCs are guaranteed over the extended temperature range (-40°C to +85°C). For pin-compatible 12-bit parts, refer to the MAX11644/MAX11645 data sheet.

## Applications

- Handheld Portable Applications
- Medical Instruments
- Battery-Powered Test Equipment
- Power-Supply Monitoring
- Solar-Powered Remote Systems
- Received-Signal-Strength Indicators
- System Supervision

*Typical Operating Circuit and Selector Guide appear at end of data sheet.*

AutoShutdown is a trademark of Maxim Integrated Products, Inc.  
 $\mu$ MAX is a registered trademark of Maxim Integrated Products, Inc.

For pricing, delivery, and ordering information, please contact Maxim Direct at 1-888-629-4642, or visit Maxim's website at [www.maxim-ic.com](http://www.maxim-ic.com).

## Features

- ♦ Ultra-Tiny 1.9mm x 2.2mm Wafer Level Package
- ♦ High-Speed I<sup>2</sup>C-Compatible Serial Interface
  - 400kHz Fast Mode
  - 1.7MHz High-Speed Mode
- ♦ Single Supply
  - 2.7V to 3.6V (MAX11647)
  - 4.5V to 5.5V (MAX11646)
- ♦ Internal Reference
  - 2.048V (MAX11647)
  - 4.096V (MAX11646)
- ♦ External Reference: 1V to V<sub>DD</sub>
- ♦ Internal Clock
- ♦ 2-Channel Single-Ended or 1-Channel Fully Differential
- ♦ Internal FIFO with Channel-Scan Mode
- ♦ Low Power
  - 670 $\mu$ A at 94.4ksps
  - 230 $\mu$ A at 40ksps
  - 60 $\mu$ A at 10ksps
  - 6 $\mu$ A at 1ksps
  - 0.5 $\mu$ A in Power-Down Mode
- ♦ Software-Configurable Unipolar/Bipolar

## Ordering Information

PART	TEMP RANGE	PIN-PACKAGE	I <sup>2</sup> C SLAVE ADDRESS
MAX11646EUA+	-40°C to +85°C	8 $\mu$ MAX	0110110

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## ABSOLUTE MAXIMUM RATINGS

V <sub>DD</sub> to GND .....	-0.3V to +6V
AIN0, AIN1,	
REF to GND .....	-0.3V to the lower of (V <sub>DD</sub> + 0.3V) and 6V
SDA, SCL to GND.....	-0.3V to +6V
Maximum Current Into Any Pin .....	±50mA
Continuous Power Dissipation (T <sub>A</sub> = +70°C)	
8-Pin µMAX (derate 4.5mW/°C above +70°C) .....	362mW
12-Pin WLP (derate 16.1mW/°C above +70°C) .....	1288mW

Operating Temperature Range .....	-40°C to +85°C
Junction Temperature .....	+150°C
Storage Temperature Range .....	-60°C to +150°C
Lead Temperature (soldering, 10s)	
µMAX only .....	+300°C
Soldering Temperature (reflow) .....	+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

Rise Time of SDA Signal	t <sub>RD</sub>	Measured from 0.3V <sub>DD</sub> to 0.7V <sub>DD</sub>	20	160	ns	
Fall Time of SDA Signal	t <sub>FD</sub>	Measured from 0.3V <sub>DD</sub> to 0.7V <sub>DD</sub> (Note 12)	20	160	ns	
Setup Time for a STOP (P) Condition	t <sub>SU:STO</sub>		160			ns
Capacitive Load for Each Bus Line	C <sub>B</sub>			400		pF
Pulse Width of Spike	t <sub>SP</sub>	(Notes 11 and 14)	0	10	ns	

**Note 1:** All WLP devices are 100% production tested at T<sub>A</sub> = +25°C. Specifications over temperature limits are guaranteed by design and characterization.

**Note 2:** For DC accuracy, the MAX11646 is tested at V<sub>DD</sub> = 5V and the MAX11647 is tested at V<sub>DD</sub> = 3V, with an external reference for both ADCs. All devices are configured for unipolar, single-ended inputs.

**Note 3:** Relative accuracy is the deviation of the analog value at any code from its theoretical value after the full-scale range and offsets have been calibrated.

**Note 4:** Offset nulled.

**Note 5:** Conversion time is defined as the number of clock cycles needed for conversion multiplied by the clock period. Conversion time does not include acquisition time. SCL is the conversion clock in the external clock mode.

**Note 6:** A filter on the SDA and SCL inputs suppresses noise spikes and delays the sampling instant.

**Note 7:** The absolute input voltage range for the analog inputs (AIN0/AIN1) is from GND to V<sub>DD</sub>.

**Note 8:** When the internal reference is configured to be available at REF (SEL[2:1] = 11), decouple REF to GND with a 0.1µF capacitor and a 2kΩ series resistor (see the *Typical Operating Circuit*).

**Note 9:** ADC performance is limited by the converter's noise floor, typically 300µV<sub>P-P</sub>.

**Note 10:** Measured as follows for the MAX11647:

$$\left[ \left[ V_{FS}(3.6V) - V_{FS}(2.7V) \right] \times \frac{2^N}{V_{REF}} \right] \\ (3.6V - 2.7V)$$

and for the MAX11646, where N is the number of bits:

$$\left[ \left[ V_{FS}(5.5V) - V_{FS}(4.5V) \right] \times \frac{2^N}{V_{REF}} \right] \\ (5.5V - 4.5V)$$

**Note 11:** A master device must provide a data hold time for SDA (referred to V<sub>IL</sub> of SCL) to bridge the undefined region of SCL's falling edge (see Figure 1).

**Note 12:** The minimum value is specified at T<sub>A</sub> = +25°C.

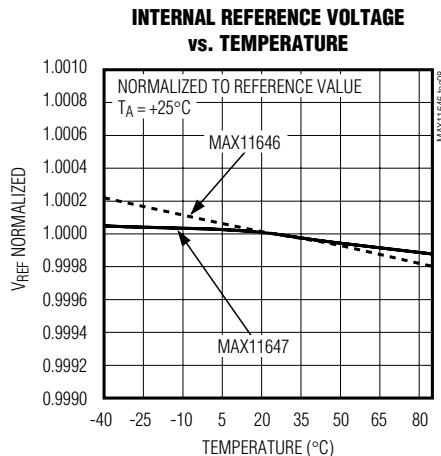

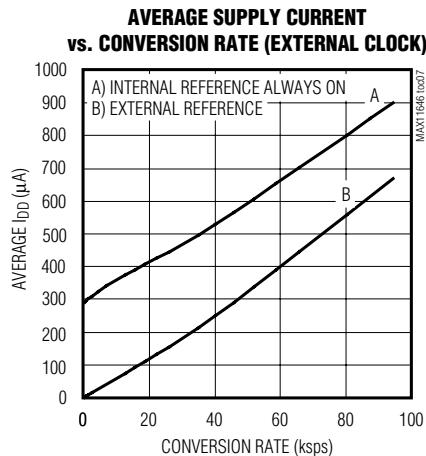

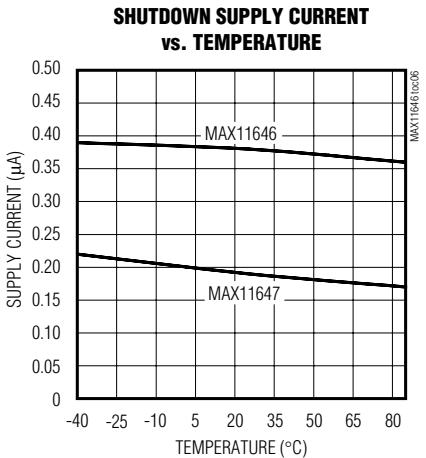

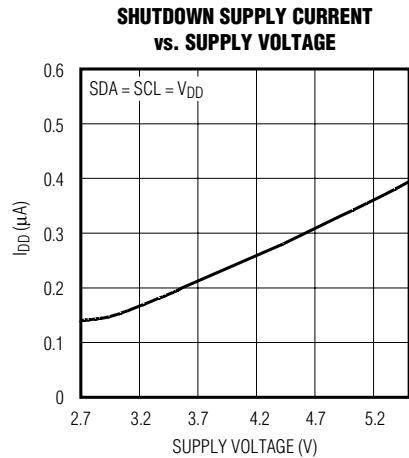

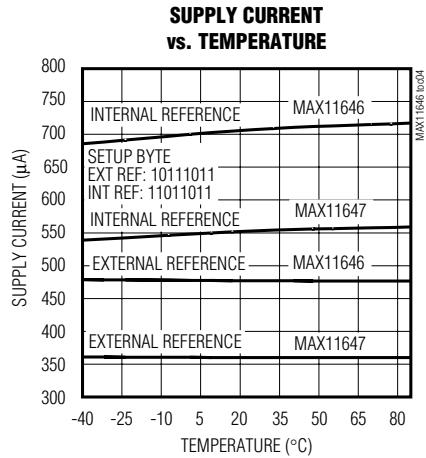

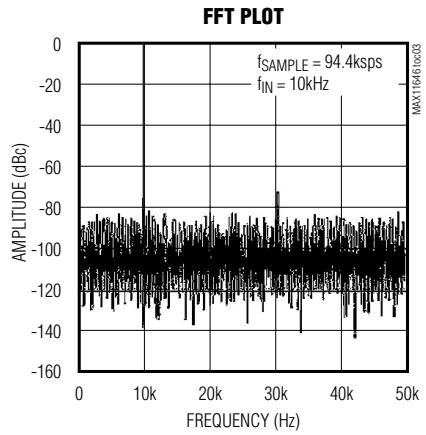

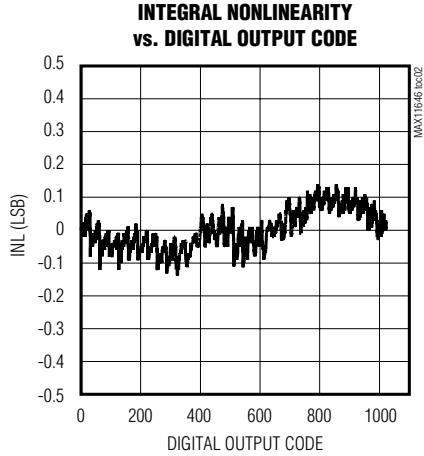

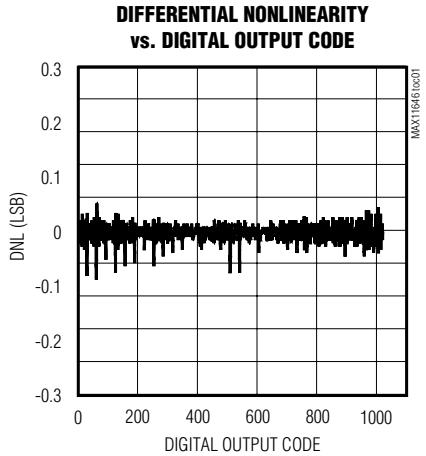

**Note 13:** C<sub>B</sub> = total capacitance of one bus line in pF.

**Note 14:** f<sub>SCL</sub> must meet the minimum clock low time plus the rise/fall times.

## Power Supply

The MAX11646/MAX11647 operate from a single supply and consume 670 $\mu$ A (typ) at sampling rates up to 94.4ksps. The MAX11647 features a 2.048V internal reference and the MAX11646 features a 4.096V internal reference. These devices can be configured for use with an external reference from 1V to V<sub>DD</sub>.

## Analog Input and Track/Hold

The MAX11646/MAX11647 analog input architecture contains an analog input multiplexer (mux), a fully differential T/H capacitor, T/H switches, a comparator, and a fully differential switched capacitive digital-to-analog converter (DAC) (Figure 4).

In single-ended mode, the analog-input multiplexer connects C<sub>T/H</sub> between the analog input selected by CS0 (see the *Configuration/Setup Bytes (Write Cycle)* section) and GND (Table 3). In differential mode, the analog input multiplexer connects C<sub>T/H</sub> to the + and - analog inputs selected by CS0 (Table 4).

During the acquisition interval, the T/H switches are in the track position and C<sub>T/H</sub> charges to the analog input signal. At the end of the acquisition interval, the T/H switches move to the hold position retaining the charge on C<sub>T/H</sub> as a stable sample of the input signal.

## Detailed Description

The MAX11646/MAX11647 ADCs use successive-approximation conversion techniques and fully differential input T/H circuitry to capture and convert an analog signal to a serial 10-bit digital output. The MAX11646/MAX11647 measure either two single-ended inputs or one differential input. These devices feature a high-speed, 2-wire serial interface supporting data rates up to 1.7MHz. Figure 2 shows the simplified internal structure for the MAX11646/MAX11647.

## Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

During the conversion interval, the switched capacitive DAC adjusts to restore the comparator input voltage to 0V within the limits of 10-bit resolution. This action requires 10 conversion clock cycles and is equivalent to transferring a charge of  $11\text{pF} \times (\text{VIN}_+ - \text{VIN}_-)$  from C<sub>T/H</sub> to the binary-weighted capacitive DAC, forming a digital representation of the analog input signal.

Sufficiently low source impedance is required to ensure an accurate sample. A source impedance of up to  $1.5\text{k}\Omega$  does not significantly degrade sampling accuracy. To minimize sampling errors with higher source impedances, connect a  $100\text{pF}$  capacitor from the analog input to GND. This input capacitor forms an RC filter with the source impedance limiting the analog-input bandwidth. For larger source impedances, use a buffer amplifier to maintain analog-input signal integrity and bandwidth.

When operating in internal clock mode, the T/H circuitry enters its tracking mode on the eighth rising clock edge of the address byte (see the *Slave Address* section). The T/H circuitry enters hold mode on the falling clock edge of the acknowledge bit of the address byte (the ninth clock pulse). A conversion or a series of conversions is then internally clocked and the MAX11646/MAX11647 hold SCL low. With external clock mode, the T/H circuitry enters track mode after a valid address on the rising edge of the clock during the read (R/W = 1) bit. Hold mode is then entered on the rising edge of the second clock pulse during the shifting out of the first byte of the result. The conversion is performed during the next 10 clock cycles.

The time required for the T/H circuitry to acquire an input signal is a function of the input sample capacitance. If the analog input source impedance is high, the acquisition time constant lengthens and more time must be allowed between conversions. The acquisition time (t<sub>ACQ</sub>) is the minimum time needed for the signal to be acquired. It is calculated by:

$$t_{\text{ACQ}} \geq 9 \times (\text{RSOURCE} + \text{RIN}) \times \text{CIN}$$

where RSOURCE is the analog input source impedance, R<sub>IN</sub> =  $2.5\text{k}\Omega$ , and C<sub>IN</sub> =  $22\text{pF}$ . t<sub>ACQ</sub> is  $1.5/\text{fSCL}$  for internal clock mode and t<sub>ACQ</sub> =  $2/\text{fSCL}$  for external clock mode.

### Analog Input Bandwidth

The MAX11646/MAX11647 feature input-tracking circuitry with a 5MHz small-signal bandwidth. The 5MHz input bandwidth makes it possible to digitize high-speed transient events and measure periodic signals with bandwidths exceeding the ADC's sampling rate by using undersampling techniques. To avoid high-frequency signals being aliased into the frequency band of interest, anti-alias filtering is recommended.

### Analog Input Range and Protection

Internal protection diodes clamp the analog input to V<sub>DD</sub> and GND. These diodes allow the analog inputs to swing from (V<sub>GND</sub> - 0.3V) to (V<sub>DD</sub> + 0.3V) without causing damage to the device. For accurate conversions the inputs must not go more than 50mV below GND or above V<sub>DD</sub>.

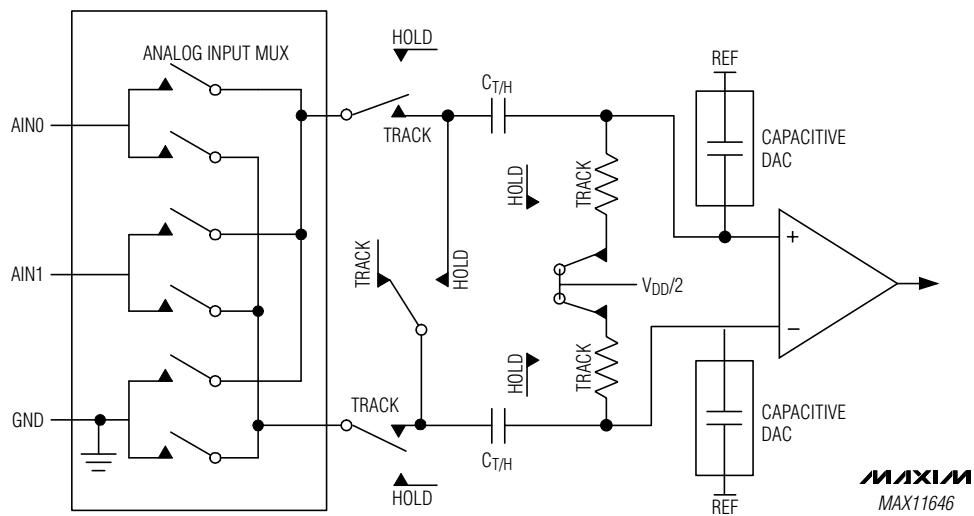

Figure 4. Equivalent Input Circuit

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## Single-Ended/Differential Input

The SGL/DIF of the configuration byte configures the MAX11646/MAX11647 analog input circuitry for single-ended or differential inputs (Table 2). In single-ended mode ( $SGL/DIF = 1$ ), the digital conversion results are the difference between the analog input selected by CS0 and GND (Table 3). In differential mode ( $SGL/DIF = 0$ ), the digital conversion results are the difference between the + and the - analog inputs selected by CS0 (Table 4).

## Unipolar/Bipolar

When operating in differential mode, the BIP/UNI bit of the setup byte (Table 1) selects unipolar or bipolar operation. Unipolar mode sets the differential input range from 0 to VREF. A negative differential analog input in unipolar mode causes the digital output code to be zero. Selecting bipolar mode sets the differential input range to  $\pm VREF/2$ . The digital output code is binary in unipolar mode and two's complement in bipolar mode. See the *Transfer Functions* section.

In single-ended mode, the MAX11646/MAX11647 always operate in unipolar mode irrespective of BIP/UNI. The analog inputs are internally referenced to GND with a full-scale input range from 0 to VREF.

## 2-Wire Digital Interface

The MAX11646/MAX11647 feature a 2-wire interface consisting of a serial-data line (SDA) and serial-clock line (SCL). SDA and SCL facilitate bidirectional communication between the MAX11646/MAX11647 and the master at rates up to 1.7MHz. The MAX11646/MAX11647 are slaves that transfer and receive data. The master (typically a microcontroller) initiates data transfer on the bus and generates the SCL signal to permit that transfer.

SDA and SCL must be pulled high. This is typically done with pullup resistors (750Ω or greater) (see the *Typical Operating Circuit*). Series resistors ( $R_S$ ) are optional. They protect the input architecture of the MAX11646/MAX11647 from high voltage spikes on the bus lines, minimize crosstalk, and undershoot of the bus signals.

## Bit Transfer

One data bit is transferred during each SCL clock cycle. A minimum of 18 clock cycles are required to transfer the data in or out of the MAX11646/MAX11647. The data on SDA must remain stable during the high period of the SCL clock pulse. Changes in SDA while SCL is stable are considered control signals (see the *START and STOP Conditions* section). Both SDA and SCL remain high when the bus is not busy.

## START and STOP Conditions

The master initiates a transmission with a START condition (S), a high-to-low transition on SDA while SCL is high. The master terminates a transmission with a STOP condition (P), a low-to-high transition on SDA while SCL is high (Figure 5). A repeated START condition (Sr) can be used in place of a STOP condition to leave the bus active and the mode unchanged (see the *HS Mode* section).

## Acknowledge Bits

Data transfers are acknowledged with an acknowledge bit (A) or a not-acknowledge bit ( $\bar{A}$ ). Both the master and the MAX11646/MAX11647 (slave) generate acknowledge bits. To generate an acknowledge, the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse (Figure 6). To generate a not-acknowledge, the receiver allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves SDA high during the high period of the clock pulse. Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer happens if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

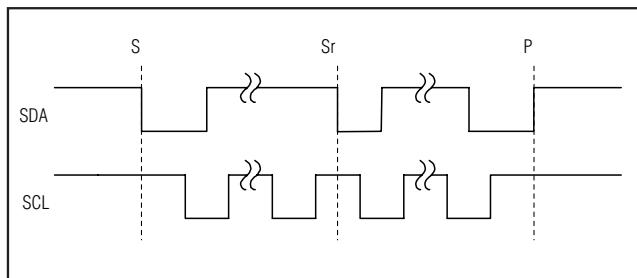

Figure 5. START and STOP Conditions

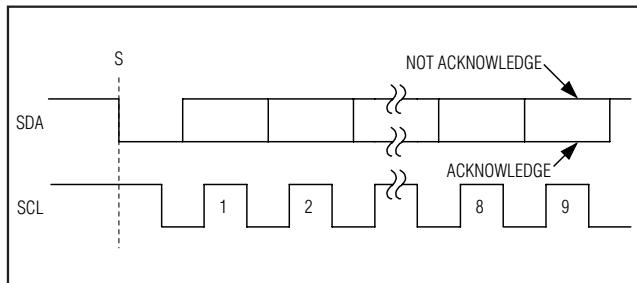

Figure 6. Acknowledge Bits

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

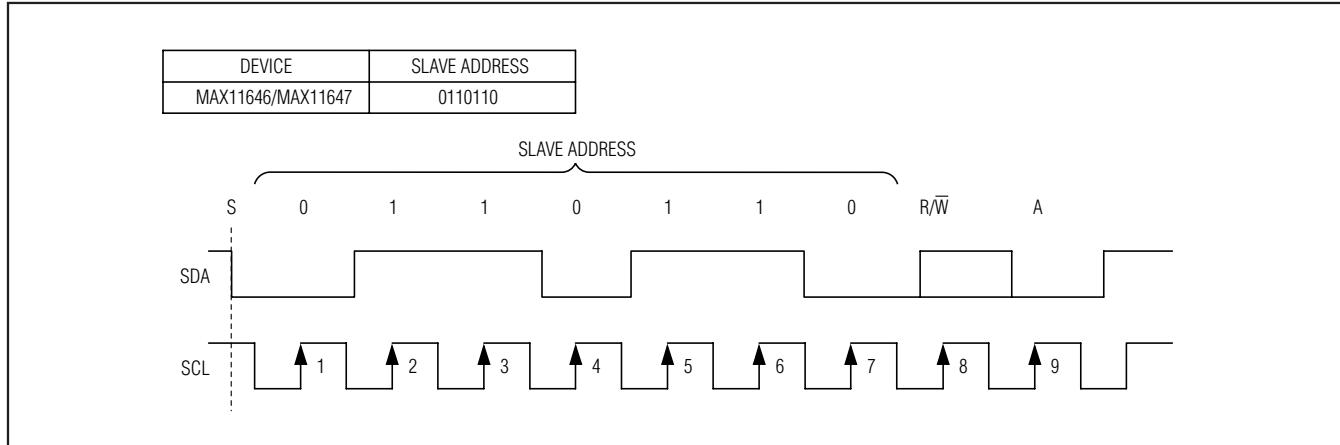

Figure 7. Slave Address Byte

### Slave Address

A bus master initiates communication with a slave device by issuing a START condition followed by a slave address. When idle, the MAX11646/MAX11647 continuously wait for a START condition followed by their slave address. When the MAX11646/MAX11647 recognize their slave address, they are ready to accept or send data. The slave address has been factory programmed and is always 0110110 for the MAX11646/MAX11647 (Figure 7). The least significant bit (LSB) of the address byte (R/W) determines whether the master is writing to or reading from the MAX11646/MAX11647 (R/W = 0 selects a write condition, R/W = 1 selects a read condition). After receiving the address, the MAX11646/MAX11647 (slave) issue an acknowledge by pulling SDA low for one clock cycle.

### Bus Timing

At power-up, the MAX11646/MAX11647 bus timing is set for fast mode (F/S mode), allowing conversion rates up to 22.2ksps. The MAX11646/MAX11647 must operate in

high-speed mode (HS mode) to achieve conversion rates up to 94.4ksps. Figure 1 shows the bus timing for the MAX11646/MAX11647's 2-wire interface.

### HS Mode

At power-up, the MAX11646/MAX11647 bus timing is set for F/S mode. The bus master selects HS mode by addressing all devices on the bus with the HS-mode master code 0000 1XXX (X = don't care). After successfully receiving the HS-mode master code, the MAX11646/MAX11647 issue a not-acknowledge, allowing SDA to be pulled high for one clock cycle (Figure 8). After the not-acknowledge, the MAX11646/MAX11647 are in HS mode. The bus master must then send a repeated START followed by a slave address to initiate HS-mode communication. If the master generates a STOP condition the MAX11646/MAX11647 return to F/S mode.

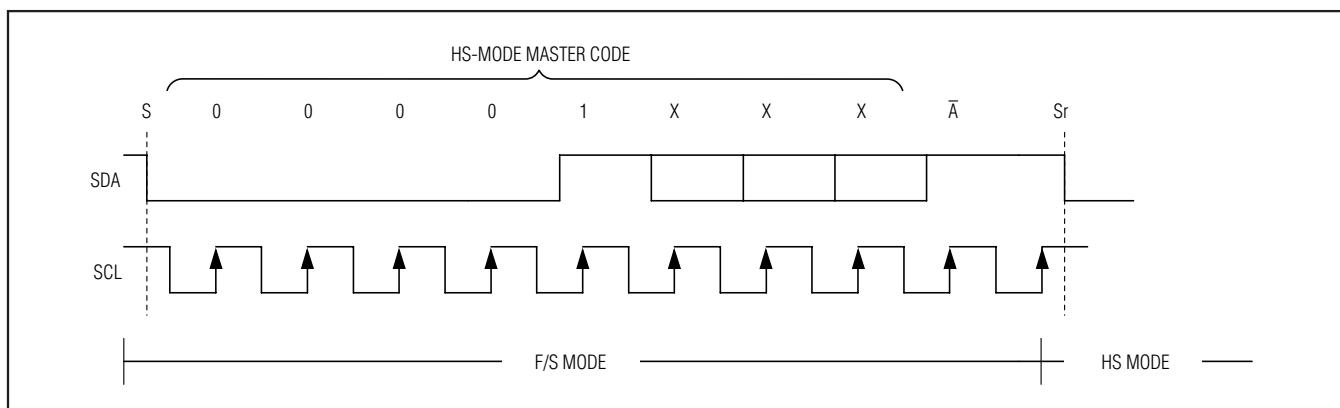

Figure 8. F/S-Mode to HS-Mode Transfer

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## Configuration/Setup Bytes (Write Cycle)

A write cycle begins with the bus master issuing a START condition followed by 7 address bits (Figure 7) and a write bit ( $R/W = 0$ ). If the address byte is successfully received, the MAX11646/MAX11647 (slave) issue an acknowledge. The master then writes to the slave. The slave recognizes the received byte as the setup byte (Table 1) if the most significant bit (MSB) is 1. If the MSB is 0, the slave recognizes that byte as the configu-

ration byte (Table 2). The master can write either 1 or 2 bytes to the slave in any order (setup byte then configuration byte, configuration byte then setup byte, setup byte or configuration byte only; see Figure 9). If the slave receives a byte successfully, it issues an acknowledge. The master ends the write cycle by issuing a STOP condition or a repeated START condition. When operating in HS mode, a STOP condition returns the bus into F/S mode (see the *HS Mode* section).

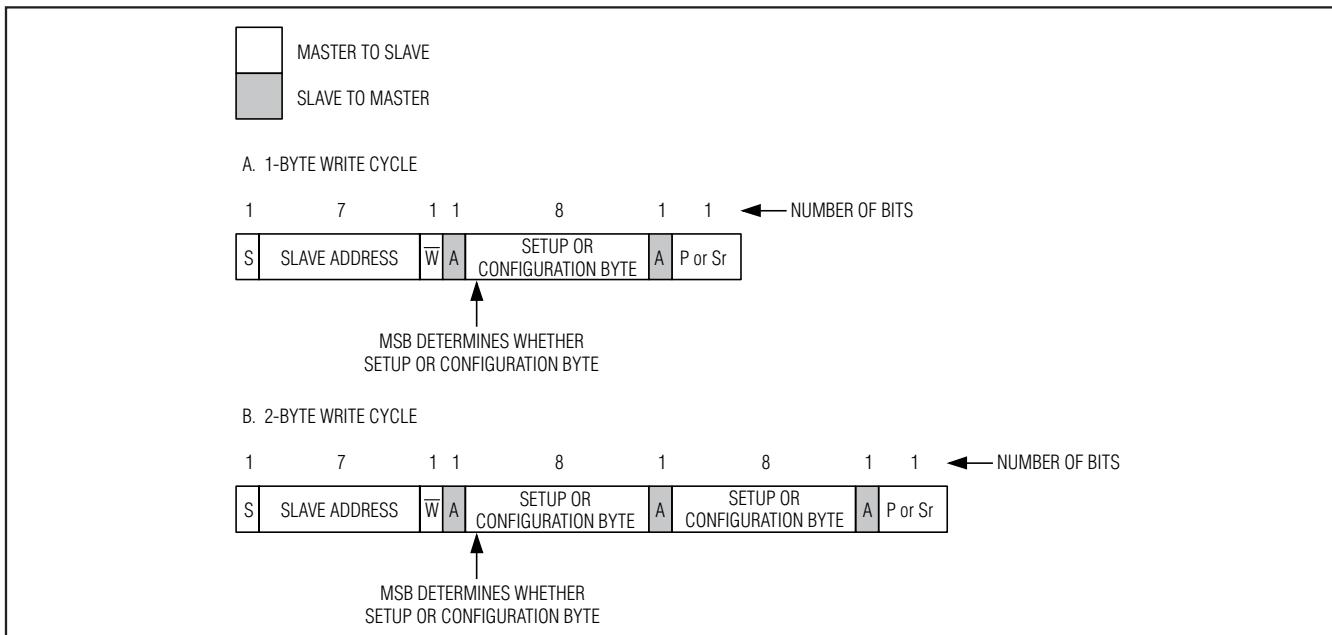

Figure 9. Write Cycle

**Table 1. Setup Byte Format**

BIT 7 (MSB)	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0 (LSB)
REG	SEL2	SEL1	SELO	CLK	BIP/UNI	$\overline{RST}$	X
<hr/>							
BIT	NAME	DESCRIPTION					
7	REG	Register bit. 1 = setup byte, 0 = configuration byte (see Table 2).					
6	SEL2	Three bits select the reference voltage (Table 6). Default to 000 at power-up.					
5	SEL1						
4	SELO						
3	CLK	1 = external clock, 0 = internal clock. Defaulted to 0 at power-up.					
2	BIP/UNI	1 = bipolar, 0 = unipolar. Defaulted to 0 at power-up (see the <i>Unipolar/Bipolar</i> section).					
1	$\overline{RST}$	1 = no action, 0 = resets the configuration register to default. Setup register remains unchanged.					
0	X	Don't-care bit. This bit can be set to 1 or 0.

CS0	AIN0	AIN1	GND
0	+		-
1		+	-

X = Don't care.

### Data Byte (Read Cycle)

A read cycle must be initiated to obtain conversion results. Read cycles begin with the bus master issuing a START condition followed by 7 address bits and a read bit (R/W = 1). If the address byte is successfully received, the MAX11646/MAX11647 (slave) issue an acknowledge. The master then reads from the slave. The result is transmitted in 2 bytes; first 6 bits of the first byte are high, then MSB through LSB are consecutively clocked out. After the master has received the byte(s), it can issue an acknowledge if it wants to continue reading or a not-acknowledge if it no longer wishes to read. If the MAX11646/MAX11647 receive a not-

0	+	-
1	-	+

X = Don't care.

acknowledge, they release SDA, allowing the master to generate a STOP or a repeated START condition. See the *Clock Modes* and *Scan Mode* sections for detailed information on how data is obtained and converted.

### Clock Modes

The clock mode determines the conversion clock and the data acquisition and conversion time. The clock mode also affects the scan mode. The state of the set-up byte's CLK bit determines the clock mode (Table 1). At power-up, the MAX11646/MAX11647 are defaulted to internal clock mode (CLK = 0).

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## Internal Clock

When configured for internal clock mode ( $\text{CLK} = 0$ ), the MAX11646/MAX11647 use their internal oscillator as the conversion clock. In internal clock mode, the MAX11646/MAX11647 begin tracking the analog input after a valid address on the eighth rising edge of the clock. On the falling edge of the ninth clock, the analog signal is acquired and the conversion begins. While converting the analog input signal, the MAX11646/MAX11647 hold SCL low (clock stretching). After the conversion completes, the results are stored in internal memory. If the scan mode is set for multiple conversions, they all happen in succession with each additional result stored in memory. The MAX11646/MAX11647 contain two 10-bit blocks of memory. Once all conversions are complete, the MAX11646/MAX11647 release SCL, allowing it to be pulled high. The master can now clock the results out of the memory in the same

order the scan conversion has been done at a clock rate of up to 1.7MHz. SCL is stretched for a maximum of  $7.6\mu\text{s}$  per channel (see Figure 10).

The device memory contains all of the conversion results when the MAX11646/MAX11647 release SCL. The converted results are read back in a first-in/first-out (FIFO) sequence. The memory contents can be read continuously. If reading continues past the result stored in memory, the pointer wraps around and point to the first result. Note that only the current conversion results are read from memory. The device must be addressed with a read command to obtain new conversion results.

The internal clock mode's clock stretching quiets the SCL bus signal, reducing the system noise during conversion. Using the internal clock also frees the bus master (typically a microcontroller) from the burden of running the conversion clock, allowing it to perform other tasks that do not need to use the bus.

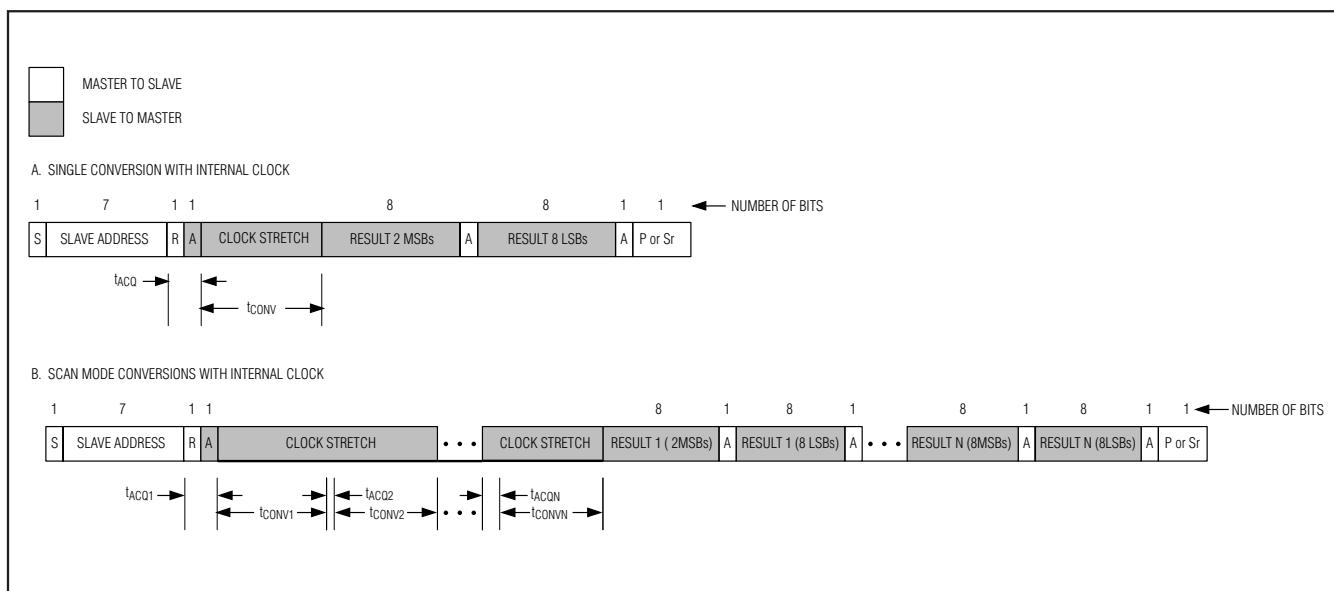

Figure 10. Internal Clock Mode Read Cycles

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## External Clock

When configured for external clock mode ( $\text{CLK} = 1$ ), the MAX11646/MAX11647 use the SCL as the conversion clock. In external clock mode, the MAX11646/MAX11647 begin tracking the analog input on the ninth rising clock edge of a valid slave address byte. Two SCL clock cycles later the analog signal is acquired and the conversion begins. Unlike internal clock mode, converted data is available immediately after the first four empty high bits. The device continuously converts input channels dictated by the scan mode until given a not acknowledge. There is no need to re-address the device with a read command to obtain new conversion results (see Figure 11).

The conversion must complete in 1ms or droop on the track-and-hold capacitor degrades conversion results. Use internal clock mode if the SCL clock period exceeds 60 $\mu$ s.

The MAX11646/MAX11647 must operate in external clock mode for conversion rates from 40ksps to 94.4ksps. Below 40ksps internal clock mode is recommended due to much smaller power consumption.

## Scan Mode

SCAN0 and SCAN1 of the configuration byte set the scan mode configuration. Table 5 shows the scanning configurations. The scanned results are written to memory in the same order as the conversion. Read the results from memory in the order they were converted. Each result needs a 2-byte transmission, the first byte begins with six empty bits during which SDA is left high. Each byte has to be acknowledged by the master or the memory transmission is terminated. It is not possible to read the memory independently of conversion.

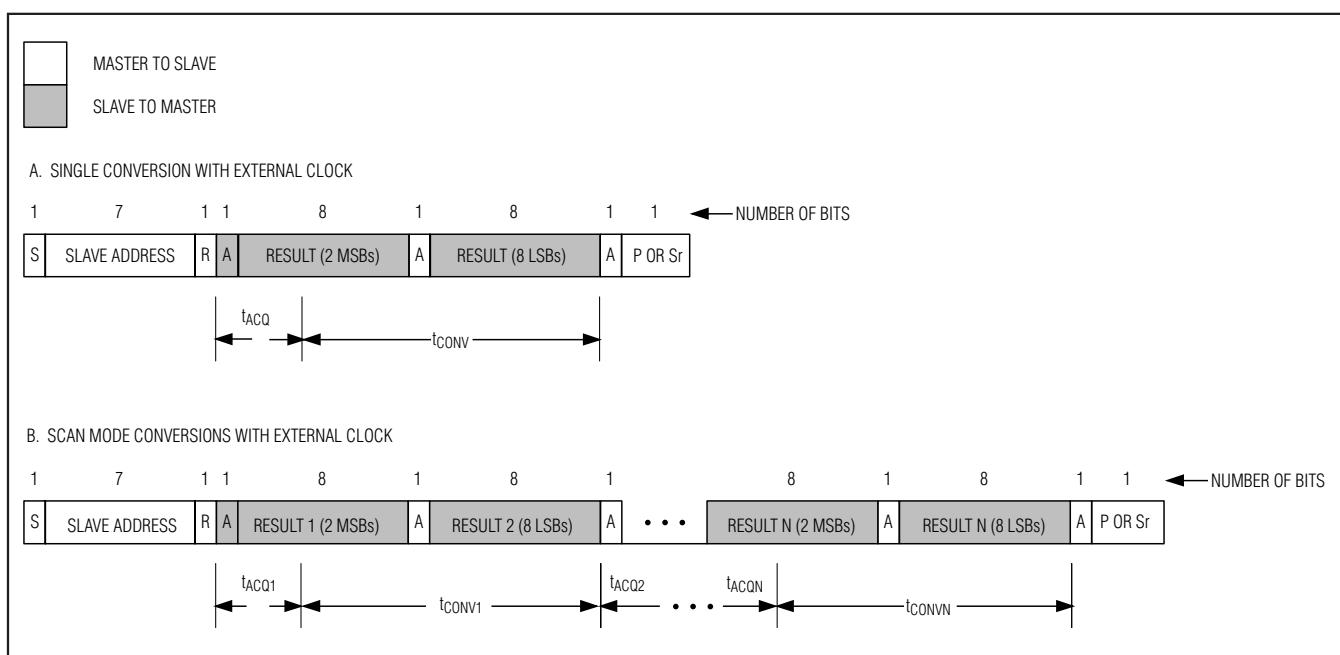

Figure 11. External Clock Mode Read Cycle

Table 5. Scanning Configuration

SCAN1	SCAN0	SCANNING CONFIGURATION
0	0	Scans up from AIN0 to the input selected by CS0.
0	1	Converts the input selected by CS0 eight times (see Tables 3 and 4).*
1	0	Reserved. Do not use.
1	1	Converts input selected by CS0.*

\*When operating in external clock mode, there is no difference between  $\text{SCAN}[1:0] = 01$  and  $\text{SCAN}[1:0] = 11$ , and converting occurs perpetually until not acknowledge occurs.

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## Applications Information

### Power-On Reset

The configuration and setup registers (Tables 1 and 2) default to a single-ended, unipolar, single-channel conversion on AIN0 using the internal clock with VDD as the reference. The memory contents are unknown after power-up.

### Automatic Shutdown

Automatic shutdown occurs between conversions when the MAX11646/MAX11647 are idle. All analog circuits participate in automatic shutdown except the internal reference due to its prohibitively long wake-up time. When operating in external clock mode, a STOP, not-acknowledge, or repeated START condition must be issued to place the devices in idle mode and benefit from automatic shutdown. A STOP condition is not necessary in internal clock mode to benefit from automatic shutdown because power-down occurs once all conversion results are written to memory (Figure 10). When using an external reference or VDD as a reference, all analog circuitry is inactive in shutdown and supply current is less than 0.5µA (typ). The digital conversion results obtained in internal clock mode are maintained in memory during shutdown and are available for access through the serial interface at any time prior to a STOP or a repeated START condition.

When idle, the MAX11646/MAX11647 continuously wait for a START condition followed by their slave address (see the Slave Address section). Upon reading a valid address byte the MAX11646/MAX11647 power up. The internal reference requires 10ms to wake up, so when using the internal reference it should be powered up 10ms prior to conversion or powered continuously. Wake-up is invisible when using an external reference or VDD as the reference.

Automatic shutdown results in dramatic power savings, particularly at slow conversion rates and with internal clock. For example, at a conversion rate of 10ksps, the average supply current for the MAX11647 is 60µA (typ) and drops to 6µA (typ) at 1ksps. At 0.1ksps the average supply current is just 1µA, or a minuscule 3µW of power consumption (see Average Supply Current vs. Conversion Rate (External Clock) in the *Typical Operating Characteristics*).

### Reference Voltage

SEL[2:0] of the setup byte (Table 1) control the reference and the REF configuration (Table 6).

### Internal Reference

The internal reference is 4.096V for the MAX11646 and 2.048V for the MAX11647. When REF is configured to be an internal reference output (SEL[2:1] = 11), decouple REF to GND with a 0.1µF capacitor and a 2kΩ series resistor (see the *Typical Operating Circuit*). Once powered up, the reference always remains on until reconfigured. The internal reference requires 10ms to wake up and is accessed using SEL0 (Table 6). When in shutdown, the internal reference output is in a high-impedance state. The reference should not be used to supply current for external circuitry. The internal reference does not require an external bypass capacitor and works best when left unconnected (SEL1 = 0).

### External Reference

The external reference can range from 1V to VDD. For maximum conversion accuracy, the reference must be able to deliver up to 40µA and have an output impedance of 500Ω or less. If the reference has a higher output impedance or is noisy, bypass it to GND as close as possible to REF with a 0.1µF capacitor.

**Table 6. Reference Voltage and REF Format**

SEL2	SEL1	SEL0	REFERENCE VOLTAGE	REF	INTERNAL REFERENCE STATE
0	0	X	V <sub>DD</sub>	Not connected	Always off
0	1	X	External reference	Reference input	Always off
1	0	0	Internal reference	Not connected*	Always off
1	0	1	Internal reference	Not connected*	Always on
1	1	0	Internal reference	Reference output	Always off
1	1	1	Internal reference	Reference output	Always on

X = Don't care.

\*Preferred configuration for internal reference.

## Transfer Functions

Output data coding for the MAX11646/MAX11647 is binary in unipolar mode and two's complement in bipolar mode with 1 LSB =  $(V_{REF}/2^N)$  where N is the number of bits (10). Code transitions occur halfway between successive-integer LSB values. Figures 12 and 13 show the input/output (I/O) transfer functions for unipolar and bipolar operations, respectively.

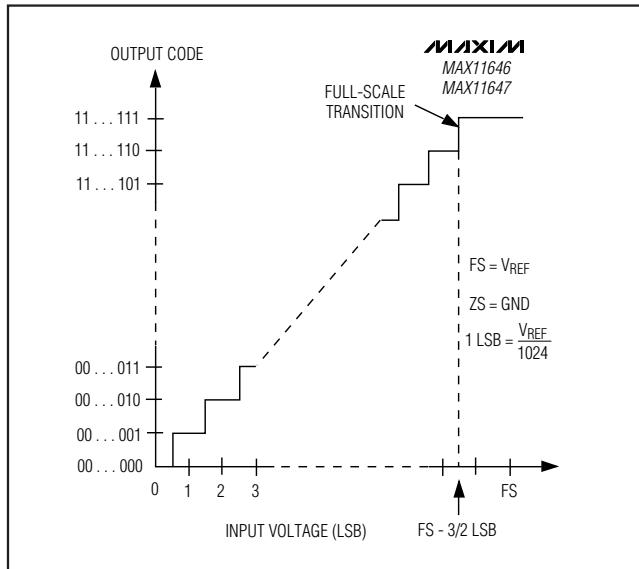

Figure 12. Unipolar Transfer Function

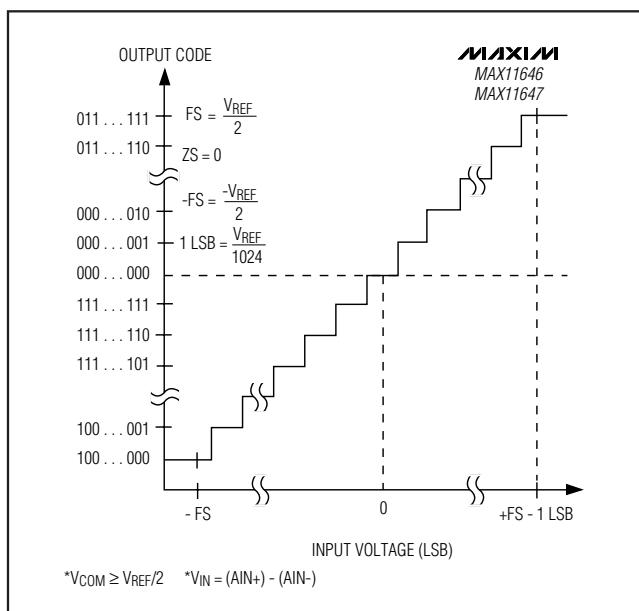

Figure 13. Bipolar Transfer Function

## Layout, Grounding, and Bypassing

Only use PCBs. Wire-wrap configurations are not recommended since the layout should ensure proper separation of analog and digital traces. Do not run analog and digital lines parallel to each other, and do not lay out digital signal paths underneath the ADC package. Use separate analog and digital PCB ground sections with only one star point (Figure 14) connecting the two ground systems (analog and digital). For lowest noise operation, ensure the ground return to the star ground's power supply is low impedance and as short as possible. Route digital signals far away from sensitive analog and reference inputs.

High-frequency noise in the power supply ( $V_{DD}$ ) could influence the proper operation of the ADC's fast comparator. Bypass  $V_{DD}$  to the star ground with a network of two parallel capacitors,  $0.1\mu F$  and  $4.7\mu F$ , located as close as possible to the MAX11646/MAX11647 power-supply pin. Minimize capacitor lead length for best supply noise rejection, and add an attenuation resistor ( $5\Omega$ ) in series with the power supply if it is extremely noisy.

## Definitions

### Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best straight-line fit or a line drawn between the end points of the transfer function, once offset and gain errors have been nullified. The MAX11646/MAX11647's INL is measured using the endpoint.

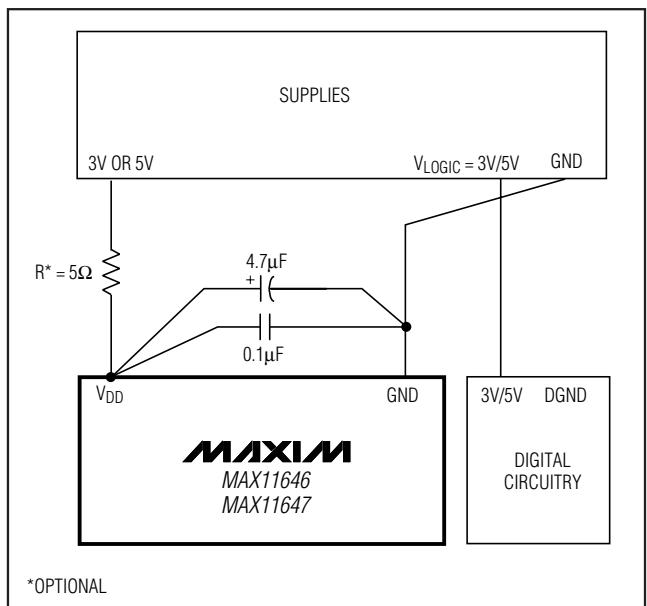

Figure 14. Power-Supply Grounding Connection

# Low-Power, 1-/2-Channel, I<sup>2</sup>C, 10-Bit ADCs in Ultra-Tiny 1.9mm x 2.2mm Package

## Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1 LSB. A DNL error specification of less than 1 LSB guarantees no missing codes and a monotonic transfer function.

## Aperture Jitter

Aperture jitter ( $t_{AJ}$ ) is the sample-to-sample variation in the time between the samples.

## Aperture Delay

Aperture delay ( $t_{AD}$ ) is the time between the falling edge of the sampling clock and the instant when an actual sample is taken.

## Signal-to-Noise Ratio

For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization error only and results directly from the ADC's resolution (N Bits):

$$\text{SNR}_{\text{MAX}}[\text{dB}] = 6.02\text{dB} \times N + 1.76\text{dB}$$

In reality, there are other noise sources besides quantization noise: thermal noise, reference noise, clock jitter, etc. SNR is computed by taking the ratio of the RMS signal to the RMS noise, which includes all spectral components minus the fundamental, the first five harmonics, and the DC offset.

## Signal-to-Noise Plus Distortion

Signal-to-noise plus distortion (SINAD) is the ratio of the fundamental input frequency's RMS amplitude to RMS equivalent of all other ADC output signals.

$$\text{SINAD (dB)} = 20 \times \log (\text{SignalRMS}/\text{NoiseRMS})$$

## Effective Number of Bits

Effective number of bits (ENOB) indicates the global accuracy of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of quantization noise only. With an input range equal to the ADC's full-scale range, calculate the ENOB as follows:

$$\text{SINAD(dB)} = 20 \times \log \left[ \frac{\text{SignalRMS}}{\text{NoiseRMS} + \text{THDRMS}} \right]$$

$$\text{ENOB} = (\text{SINAD} - 1.76)/6.02$$

## Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the RMS sum of the input signal's first five harmonics to the fundamental itself. This is expressed as:

$$\text{THD} = 20 \times \log \left( \sqrt{\left( \frac{V_2^2 + V_3^2 + V_4^2 + V_5^2}{V_1^2} \right)} \right)$$

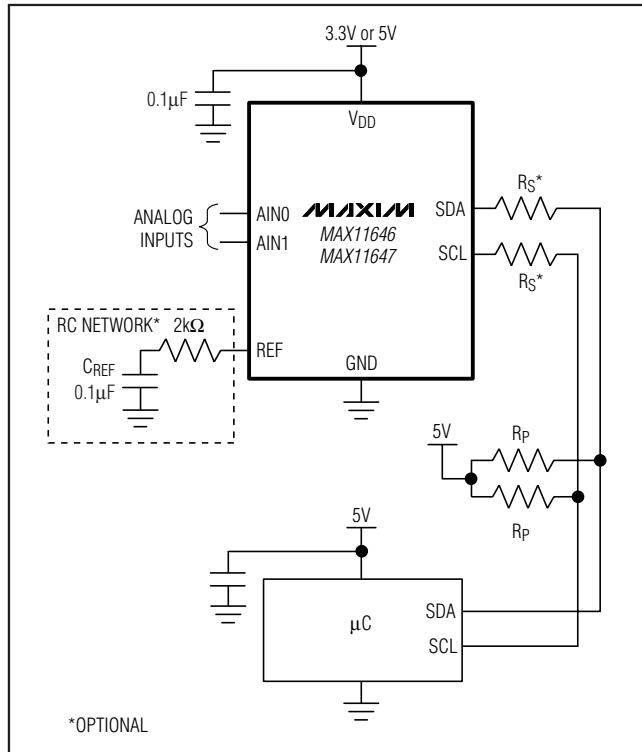

where  $V_1$  is the fundamental amplitude, and  $V_2$  through  $V_5$  are the amplitudes of the 2nd through 5th order harmonics.

## Spurious-Free Dynamic Range

Spurious-free dynamic range (SFDR) is the ratio of RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next largest distortion component.
