Quad Analog Switch/ Multiplexer/Demultiplexer with LSTTL Compatible Inputs

High-Performance Silicon-Gate CMOS

The MC74HCT4066A utilizes silicon-gate CMOS technology to achieve fast propagation delays, low ON resistances, and low OFF-channel leakage current. This bilateral switch/multiplexer/demultiplexer controls analog and digital voltages that may vary across the full power-supply range (from V_{CC} to GND).

The HCT4066A is identical in pinout to the metal–gate CMOS MC14016 and MC14066. Each device has four independent switches. The device has been designed so the ON resistances (R_{ON}) are more linear over input voltage than R_{ON} of metal–gate CMOS analog switches.

The ON/OFF control inputs are compatible with standard CMOS and LSTTL outputs. For analog switches with voltage–level translators, see the HC4316A.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range GND \leq (V_{in} or V_{out}) \leq V_{CC} .

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either GND or V_{CC}). Unused outputs must be left open. I/O pins must be connected to a properly terminated line or bus.

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

APPLICATION INFORMATION

Unused analog inputs/outputs may be left floating (not connected). However, it is advisable to tie unused analog inputs and outputs to $V_{\rm CC}$ or GND through a low value resistor. This minimizes crosstalk and feedthrough noise that may be picked–up by the unused I/O pins.

The maximum analog voltage swings are determined by the supply voltages V_{CC} and GND. The positive peak analog voltage should not exceed V_{CC} . Similarly, the negative peak analog voltage should not go below GND. In the example below, the difference between V_{CC} and GND is twelve volts. Therefore, using the configuration in Figure 16, a maximum analog signal of twelve volts peak-to-peak can be controlled.

When voltage transients above V_{CC} and/or below GND are anticipated on the analog channels, external diodes (Dx) are recommended as shown in Figure 17. These diodes should be small signal, fast turn-on types able to absorb the maximum anticipated current surges during clipping. An alternate method would be to replace the Dx diodes with MOSORB® (MOSORB is an acronym for high current surge protectors). MOSORBs are fast turn-on devices ideally suited for precise DC protection with no inherent wear out mechanism.
