## 5. Handling Devices

### 5.1 Preventing Latch-up

Latch-up may occur in a CMOS IC if a voltage higher than ( $V_{DD5}$ ,  $V_{DD35}$  or  $HV_{DD5}$ <sup>[1]</sup>) or less than ( $V_{SS5}$  or  $HV_{SS5}$ <sup>[1]</sup>) is applied to an input or output pin or if a voltage exceeding the rating is applied between the power supply pins and ground pins. If latch-up occurs, the power supply current increases rapidly, sometimes resulting in thermal breakdown of the device. Therefore, be very careful not to apply voltages in excess of the absolute maximum ratings.

**Note:** 1.  $HV_{DD5}$ ,  $HV_{SS5}$  are available only on devices having Stepper Motor Controller.

### 5.2 Handling of Unused Input Pins

If unused input pins are left open, abnormal operation may result. Any unused input pins should be connected to pull-up or pull-down resistor (2KΩ to 10KΩ) or enable internal pullup or pulldown resistors (PPER/PPCR) before the input enable (PORTEN) is activated by software. The mode pins MD\_x can be connected to  $V_{SS5}$  or  $V_{DD5}$  directly. Unused ALARM input pins can be connected to  $AV_{SS5}$  directly.

### 5.3 Power Supply Pins

In CY91460 series, devices including multiple power supply pins and ground pins are designed as follows; pins necessary to be at the same potential are interconnected internally to prevent malfunctions such as latch-up. All of the power supply pins and ground pins must be externally connected to the power supply and ground respectively in order to reduce unnecessary radiation, to prevent strobe signal malfunctions due to the ground level rising and to follow the total output current ratings. Furthermore, the power supply pins and ground pins of the CY91460 series must be connected to the current supply source via a low impedance. It is also recommended to connect a ceramic capacitor of approximately 0.1 μF as a bypass capacitor between power supply pin and ground pin near this device. This series has a built-in step-down regulator. Connect a bypass capacitor of 4.7 μF (use a X7R ceramic capacitor) to VCC18C pin for the regulator.

### 5.4 Crystal Oscillator Circuit

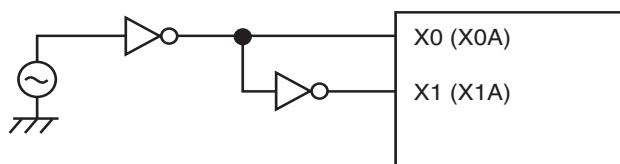

Noise in proximity to the X0 (X0A) and X1 (X1A) pins can cause the device to operate abnormally. Printed circuit boards should be designed so that the X0 (X0A) and X1 (X1A) pins, and crystal oscillator, as well as bypass capacitors connected to ground, are located near the device and ground.

It is recommended that the printed circuit board layout be designed such that the X0 and X1 pins or X0A and X1A pins are surrounded by ground plane for the stable operation. Please request the oscillator manufacturer to evaluate the oscillational characteristics of the crystal and this device.

### 5.5 Notes on Using External Clock

When using the external clock, it is necessary to simultaneously supply the X0 (X0A) and the X1 (X1A) pins. In the described combination, X1 (X1A) should be supplied with a clock signal which has the opposite phase to the X0 (X0A) pins. At X0 and X1, a frequency up to 16 MHz is possible.

**Figure 1. Example of Using Opposite Phase Supply**

## 5.6 Mode Pins (MD\_x)

These pins should be connected directly to the power supply or ground pins. To prevent the device from entering test mode accidentally due to noise, minimize the lengths of the patterns between each mode pin and power supply pin or ground pin on the printed circuit board as possible and connect them with low impedance.

## 5.7 Notes on Operating in PLL Clock Mode

If the oscillator is disconnected or the clock input stops when the PLL clock is selected, the microcontroller may continue to operate at the free-running frequency of the self-oscillating circuit of the PLL. However, this self-running operation cannot be guaranteed.

## 5.8 Pull-up Control

The AC standard is not guaranteed in case a pull-up resistor is connected to the pin serving as an external bus pin.

## 6. Notes on Debugger

### 6.1 Execution of the RETI Command

If single-step execution is used in an environment where an interrupt occurs frequently, the corresponding interrupt handling routine will be executed repeatedly to the exclusion of other processing. This will prevent the main routine and the handlers for low priority level interrupts from being executed (For example, if the time-base timer interrupt is enabled, stepping over the RETI instruction will always break on the first line of the time-base timer interrupt handler).

Disable the corresponding interrupts when the corresponding interrupt handling routine no longer needs debugging.

### 6.2 Break Function

If the range of addresses that cause a hardware break (including event breaks) is set to the address of the current system stack pointer or to an area that contains the stack pointer, execution will break after each instruction regardless of whether the user program actually contains data access instructions.

To prevent this, do not set (word) access to the area containing the address of the system stack pointer as the target of the hardware break (including an event breaks).

### 6.3 Operand Break

It may cause malfunctions if a stack pointer exists in the area which is set as the DSU operand break. Do not set the access to the areas containing the address of system stack pointer as a target of data event break.

### 6.4 Notes on PS Register

As the PS register is processed in advance by some instructions, when the debugger is being used, the exception handling may result in execution breaking in an interrupt handling routine or the displayed values of the flags in the PS register being updated. As the microcontroller is designed to carry out reprocessing correctly upon returning from such an EIT event, the operation before and after the EIT always proceeds according to specification.

■ **The following behavior may occur if any of the following occurs in the instruction immediately after a DIV0U/DIV0S instruction:**

- (a) a user interrupt or NMI is accepted;
- (b) single-step execution is performed;
- (c) execution breaks due to a data event or from the emulator menu.

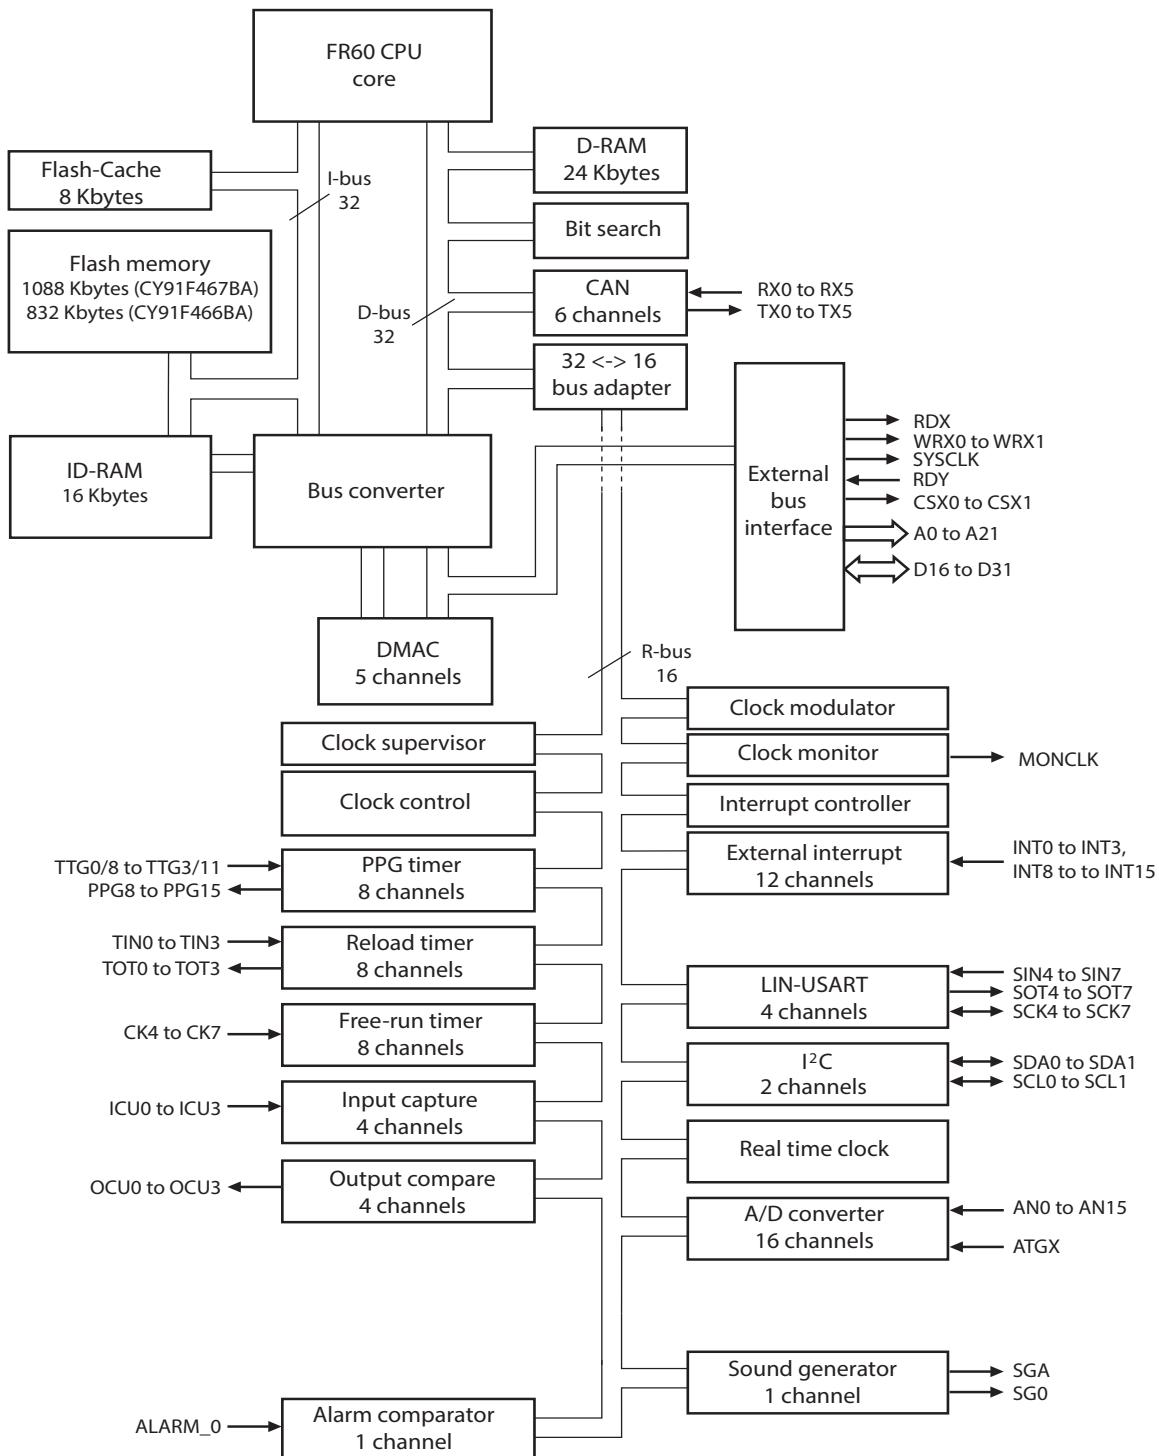

1. D0 and D1 flags are updated in advance.
2. An EIT handling routine (user interrupt/NMI or emulator) is executed.
3. Upon returning from the EIT, the DIV0U/DIV0S instruction is executed and the D0 and D1 flags are updated to the same values as those in 1.

■ **The following behavior occurs when an ORCCR, STILM, MOV Ri,PS instruction is executed to enable a user interrupt or NMI source while that interrupt is in the active state.**

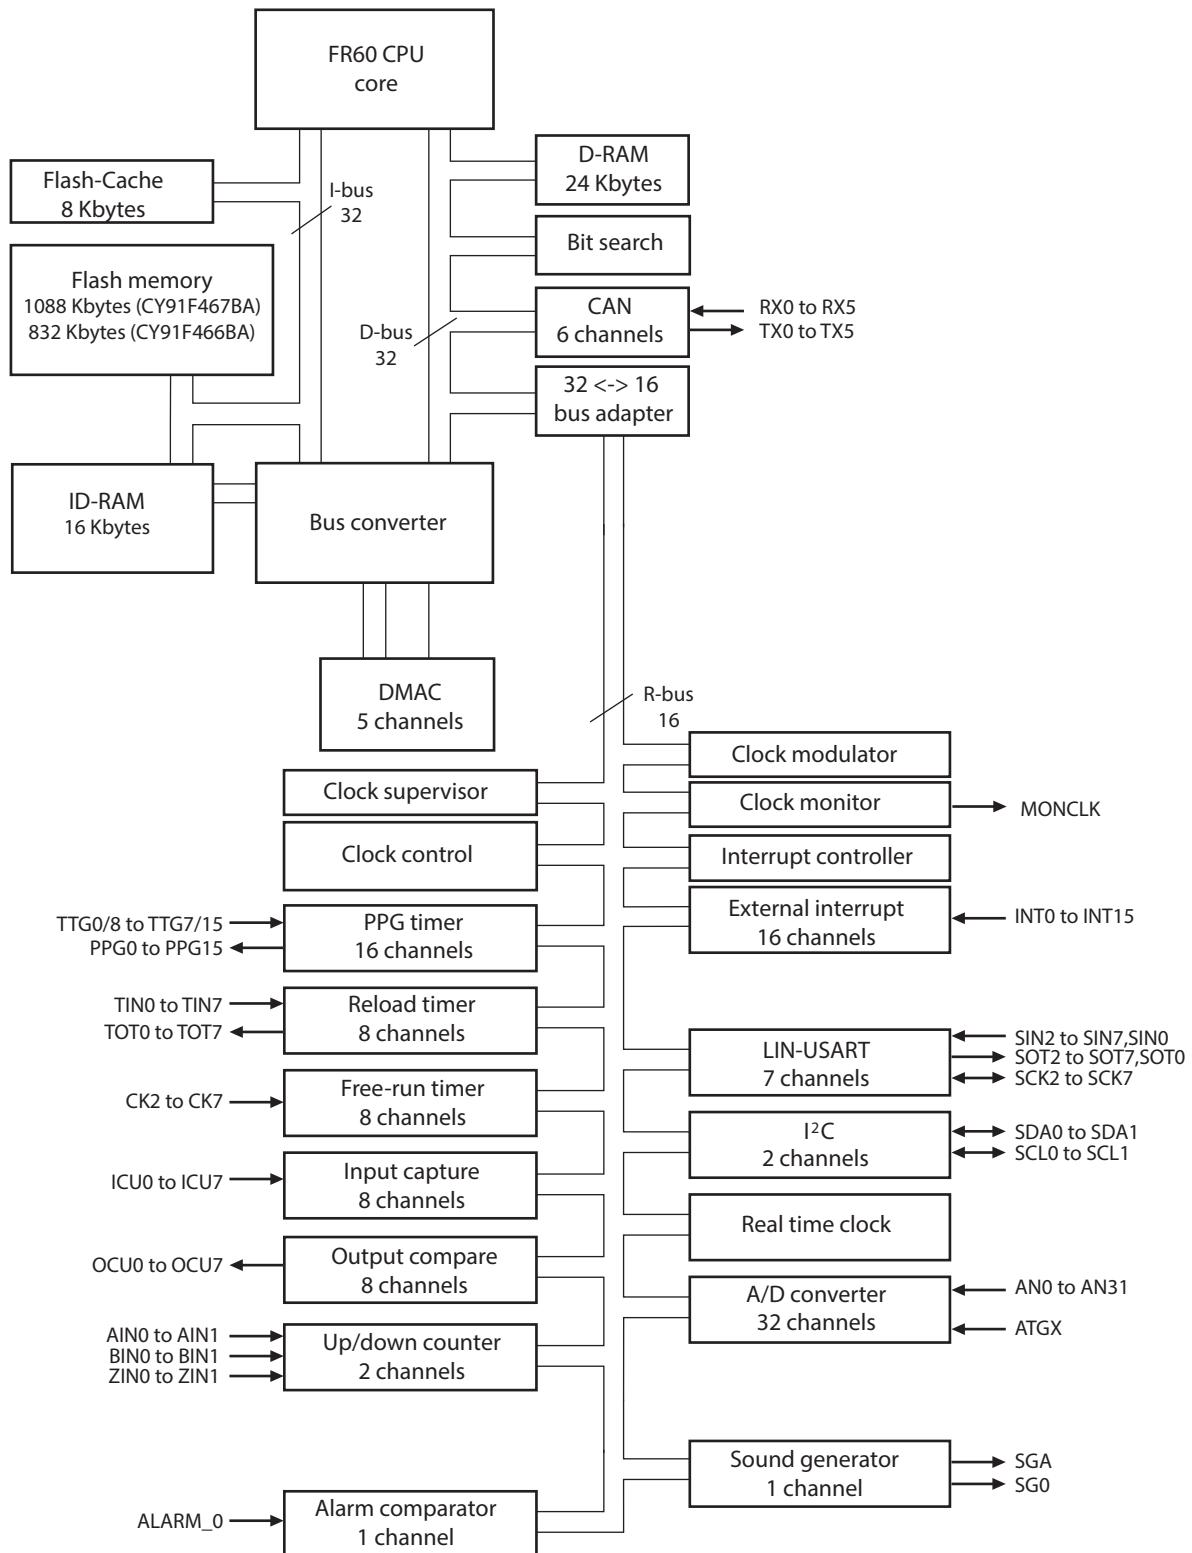

1. The PS register is updated in advance.
2. An EIT handling routine (user interrupt/NMI or emulator) is executed.
3. Upon returning from the EIT, the above instructions are executed and the PS register is updated to the same value as in 1.

## 8.3 Programming Model

### 8.3.1 Basic Programming Model

## 8.4 Registers

R13 : Virtual accumulator

R14 : Frame pointer

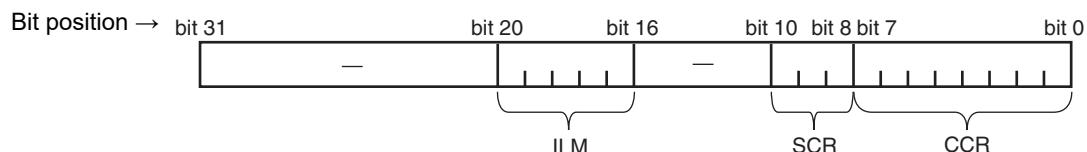

R15 : Stack pointer

Initial values at reset are undefined for R0 to R14. The value for R15 is 00000000<sub>H</sub> (SSP value).

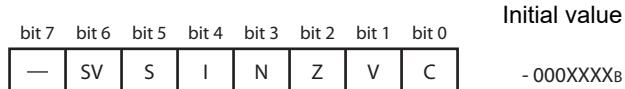

### 8.4.2 PS (Program Status)

This register holds the program status, and is divided into three parts, ILM, SCR, and CCR.

All undefined bits (-) in the diagram are reserved bits. The read values are always "0". Write access to these bits is invalid.

### 8.4.3 CCR (Condition Code Register)

SV: Supervisor flag

S: Stack flag

I: Interrupt enable flag

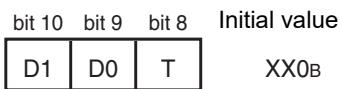

N: Negative enable flag

Z: Zero flag

V: Overflow flag

C: Carry flag

### 8.4.4 SCR (System Condition Register)

#### 8.4.8 RP (Return Pointer)

The return pointer stores the address for return from subroutines.

During execution of a CALL instruction, the PC value is transferred to this RP register.

During execution of a RET instruction, the contents of the RP register are transferred to PC.

The initial value at reset is undefined.

#### 8.4.9 USP (User Stack Pointer)

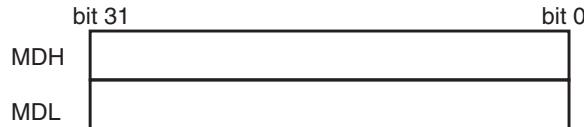

The user stack pointer, when the S flag is “1”, this register functions as the R15 register.

■ The USP register can also be explicitly specified.

#### 9.4.2 Pin Connections in Parallel Programming Mode

Resetting after setting the MD[2:0] pins to [111] will halt CPU functioning. At this time, the Flash memory's interface circuit enables direct control of the Flash memory unit from external pins by directly linking some of the signals to GP-Ports. Please see table below for signal mapping.

In this mode, the Flash memory appears to the external pins as a stand-alone unit. This mode is generally set when writing/erasing using the parallel Flash programmer. In this mode, all operations of the 8.5 Mbits Flash memory's Auto Algorithms are available.

## 9.5 Poweron Sequence in Parallel Programming Mode

The flash memory can be accessed in programming mode after a certain wait time, which is needed for Security Vector fetch:

- Minimum wait time after VDD5/VDD5R power on: 2.76 ms
- Minimum wait time after INITX rising: 1.0 ms

## 9.6 Flash Security

### 9.6.1 Vector Addresses

Two Flash Security Vectors (FSV1, FSV2) are located parallel to the Boot Security Vectors (BSV1, BSV2) controlling the protection functions of the Flash Security Module:

FSV1: 0x14:8000	BSV1: 0x14:8004
FSV2: 0x14:8008	BSV2: 0x14:800C

### 9.6.2 Security Vector FSV1

The setting of the Flash Security Vector FSV1 is responsible for the read and write protection modes and the individual write protection of the 8 KBytes sectors.

#### 9.6.2.1 FSV1 (bit31 to bit16)

The setting of the Flash Security Vector FSV1 bits [31:16] is responsible for the read and write protection modes.

**Table 2. Explanation of the bits in the Flash Security Vector FSV1[31:16]**

### 9.6.2.2 FSV1 (bit15 to bit0) CY91F467BA/466BA

The setting of the Flash Security Vector FSV1 bits [15:0] is responsible for the individual write protection of the 8 KBytes sectors. It is only evaluated if write protection bit FSV1[17] is set.

**Table 3. Explanation of the Bits in the Flash Security Vector FSV1[15:0]**

FSV1 bit	Sector	Enable Write Protection	Disable Write Protection	Comment
FSV1[0]	SA0	set to "0"	set to "1"

**Note:** It is mandatory to always set the sector where the Flash Security Vectors FSV1 and FSV2 are located to write protected (here sector SA4). Otherwise it is possible to overwrite the Security Vector to a setting where it is possible to either read out the Flash content or manipulate data by writing. See section “Flash access in CPU mode” for an overview about the sector organisation of the Flash Memory.

### 9.6.2.3 FSV1 (bit15 to bit0) CY91F465BB/464BB

The setting of the Flash Security Vector FSV1 bits [15:0] is responsible for the individual write protection of the 8 KBytes sectors. It is only evaluated if write protection bit FSV1[17] is set.

See section “Flash access in CPU mode” for an overview about the sector organisation of the Flash Memory.

### 9.6.3 Security Vector FSV2 CY91F467BA/466BA

The setting of the Flash Security Vector FSV2 bits [31:0] is responsible for the individual write protection of the 64 KByte sectors. It is only evaluated if write protection bit FSV1[17] is set.

**Table 5. Explanation of the Bits in the Flash Security Vector FSV2[31:0]**

## 10. Memory Space

The FR family has 4 Gbytes of logical address space ( $2^{32}$  addresses) available to the CPU by linear access.

- Direct addressing area

The following address space area is used for I/O.

This area is called direct addressing area, and the address of an operand can be specified directly in an instruction.

The size of directly addressable area depends on the length of the data being accessed as shown below.

Byte data access:  $000_H$  to  $0FF_H$

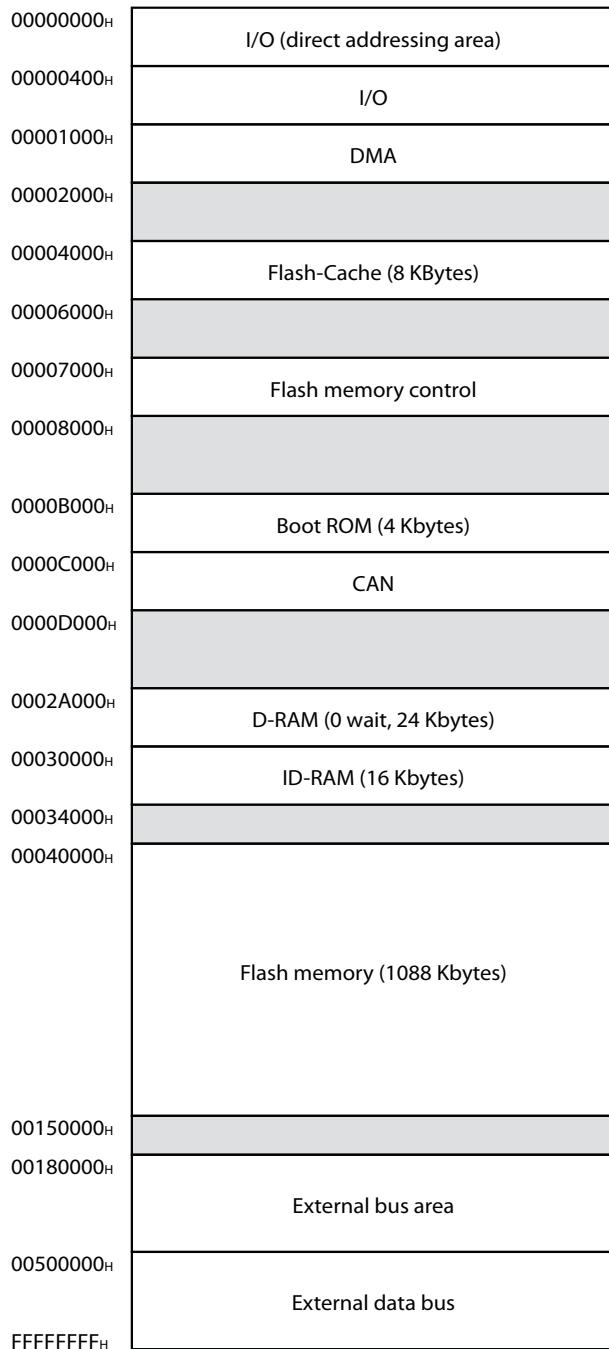

Half word access:  $000_H$  to  $1FF_H$

Word data access:  $000_H$  to  $3FF_H$

- The Interrupt Control Registers (ICRs) are located in the interrupt controller and set the interrupt level for each interrupt request. An ICR is provided for each interrupt request.
- The vector address for each EIT (exception, interrupt or trap) is calculated by adding the listed offset to the table base register value (TBR). The TBR specifies the top of the EIT vector table. The addresses listed in the table are for the default TBR value (000FFC00H). The TBR is initialized to this value by a reset. The TBR is set to 000FFC00H after the internal boot ROM is executed.
- ICR23 and ICR47 can be exchanged by setting the REALOS compatibility bit (addr 0C03H : IOS[0])
- Used by REALOS
- Memory Protection Unit (MPU) support

## 14.2 Clock Modulator settings

The following table shows all possible settings for the Clock Modulator in a base clock frequency range from 32MHz up to 88MHz. The Flash access time settings need to be adjusted according to Fmax while the PLL and clock gear settings should be set according to base clock frequency.

1. The parameter is based on  $V_{SS5} = AV_{SS5} = 0.0$  V.

2.  $AV_{CC5}$  and  $AVRH5$  must not exceed  $V_{DD5} + 0.3$  V.

3.

- Use within recommended operating conditions.
- Use with DC voltage (current).
- +B signals are input signals that exceed the  $V_{DD5}$  voltage. +B signals should always be applied by connecting a limiting resistor between the +B signal and the microcontroller.
- The value of the limiting resistor should be set so that the current input to the microcontroller pin does not exceed the rated value at any time, either instantaneously or for an extended period, when the +B signal is input.
- Note that when the microcontroller drive current is low, such as in the low power consumption modes, the +B input potential can increase the potential at the power supply pin via a protective diode, possibly affecting other devices.
- Note that if the +B signal is input when the microcontroller is off (not fixed at 0 V), power is supplied through the +B input pin; therefore, the microcontroller may partially operate.
- Note that if the +B signal is input at power-on, since the power is supplied through the pin, the power-on reset may not function in the power supply voltage.
- Do not leave +B input pins open.

**Figure 2. Example of Recommended Circuit :**

4. Maximum output current is defined as the value of the peak current flowing through any one of the corresponding pins.
5. Average output current is defined as the value of the average current flowing through any one of the corresponding pins for a 100 ms period.
6. Total average output current is defined as the value of the average current flowing through all of the corresponding pins for a 100 ms period.
7. The maximum permitted power dissipation depends on the ambient temperature, the air flow velocity and the thermal conductance of the package on the PCB.

The actual power dissipation depends on the customer application and can be calculated as follows:

$$P_D = P_{IO} + P_{INT}$$

$$P_{IO} = \sum (V_{OL} * I_{OL} + V_{OH} * I_{OH}) \text{ (IO load power dissipation, sum is performed on all IO ports)}$$

$$P_{INT} = V_{DD5R} * I_{CC} + AV_{CC5} * I_A + AVR_{H5} * I_R \text{ (internal power dissipation)}$$

8. Worst case value for the QFP package mounted on a 4-layer PCB at specified  $T_A$  without air flow.

9. Please contact Cypress for reliability limitations when using under these conditions.

**WARNING:** Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

**WARNING:** The recommended operating conditions are required in order to ensure the normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.

Always use semiconductor devices within their recommended operating condition ranges. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their representatives beforehand.
